

# Underwater UXO targets detection, mapping and classification from onepass dynamic data sets

Project Number MR23-9000

Principal Investigator: Fridon Shubitidze

PI's Organization: Dartmouth College

In Progress Review Meeting

01/14/2026

# Project Team

**Dr. Fridon Shubitidze**

*Thayer School of Engineering,  
Dartmouth College*

## Grad Student

Mr. Maximilian Orman-  
Kollmar

- Military Installation  
Contact: SERDP-  
ESTC

# Overview:

- The project's objectives:
  - Determine feasibility of using one-pass dynamic UW EMI sensors data sets for targets detection and classification
  - Understand and mitigate the sensor motion/orientation effects.
  - Process UW dynamic data sets.
  - Assess classification performance.

# Bottom Line Up Front

- **Goal:** Evaluate the applicability of UW EMI systems and data processing algorithms for detecting, locating, and classifying UW targets using single-pass EMI data set.
- **Technologies tested**
  - Advanced EMI signal-processing algorithms applied to raw ULTRATEMA datasets collected at a U.S. Navy site.
  - Innovative noise-filtering techniques were tested for background noise and unexpected, non-physical signal spikes removal.
  - Forward and inverse EMI modeling frameworks were employed for data inversion and target classification.
- **Results:**
  - Data spikes and background noise were successfully removed, resulting in improved target detection performance.
  - Robust target-classification features were extracted, and detected anomalies were classified.
- **Challenges:**
  - Variability in UW geolocation accuracy, combined with EMI sensor signal spikes, has the potential to degrade data quality and pose significant challenges for targets classification.
- **Support needed**
  - Ground-truth data are required to fully assess and validate the classification performance of the developed algorithms.

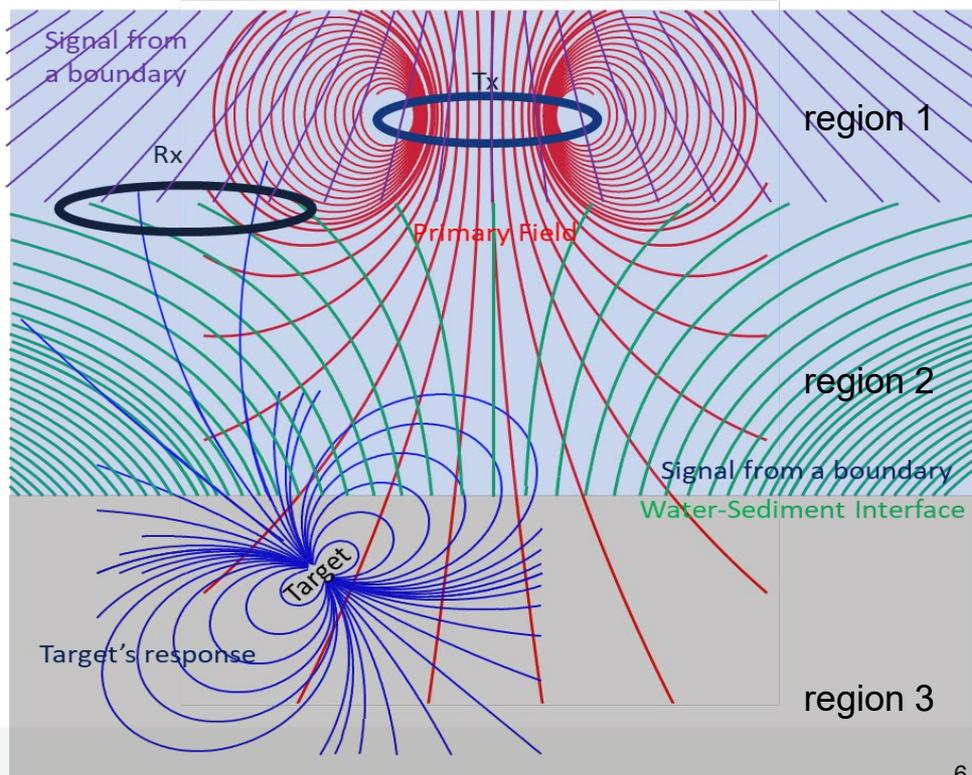

# Site Description

- The data for this demonstration were collected at a U.S. Navy site using the ULTRATEMA sensor.
- The demonstration area was divided into three sections, with each section further subdivided into shallow and deep zones.
- For this deployment, the ULTRATEMA system used a slightly modified transmitter configuration, operating with three Tx coils instead of the four used in earlier demos.
- The data were delivered as ascii files with multiple formats.

# EMI sensing in underwater environment

Air-Water Interface

- The total field in Region 2 is the sum of the fields produced by the transmitter coil (response from water), reflected fields from boundaries, and fields from a target.
- The fields in Region 1 are the transmitted fields.
- The total field in Region 3 is the sum of the transmitted fields and the response from a target.
- During dynamic data collection mode, the Rx coils move within a time-varying magnetic field, resulting in additional motion-induced signals.

# Technical Approach

Task 1: Select Bkg removal model

Task 2: Adapt Adv. Signal processing algorithm to UW data

Task 3: Apply to UW EMI data sets

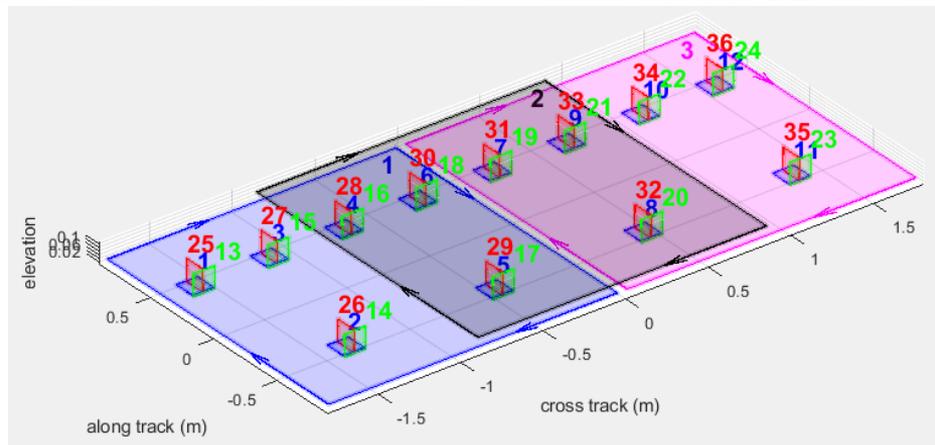

Task 4: Optimize models

Task 5: Process UW dynamic datasets and evaluate the performance of models for UW target classification.

# Performance Objectives

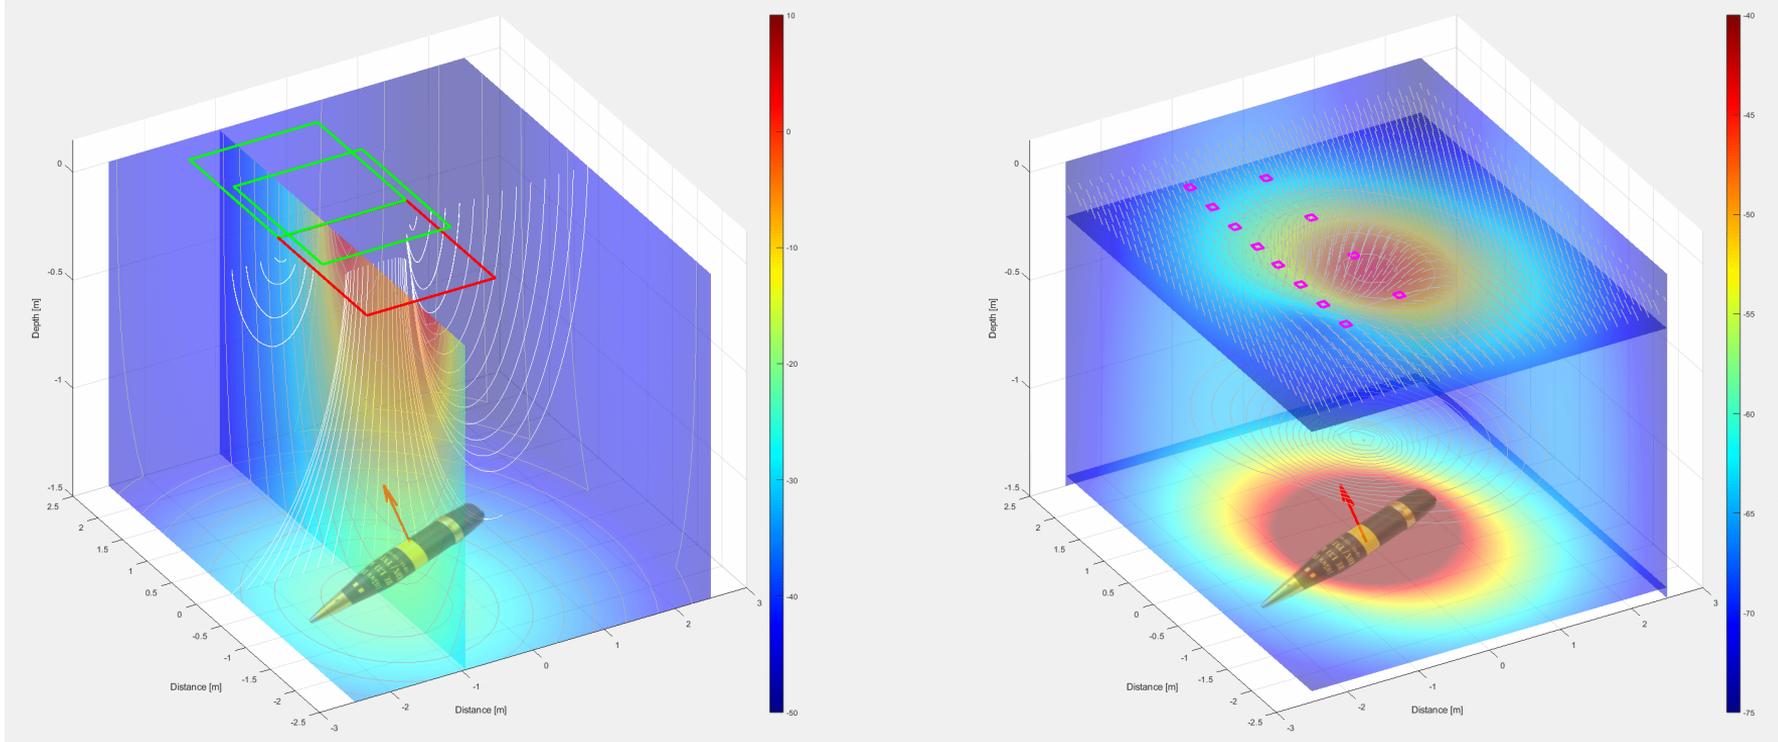

Performance Objective	Data Requirements	Success Criteria
<b>Quantitative Performance Objectives</b>		
UW anomalies detection	UW blind data set and GT	<ul style="list-style-type: none"> <li>•All anomalies located within 20 times their diameter from the transmitter are detected.</li> </ul>
Accuracy of locating all seeded UW targets	Targets GPS locations	<ul style="list-style-type: none"> <li>•Less than 0.75 meters distance between actual and predicted locations for buried anomalies.</li> <li>•less than 3.5 meters for proud and surface anomalies.</li> </ul>
Targets classification	UW blind data set and TOI information	<ul style="list-style-type: none"> <li>•All detected Targets of Interest (TOI) are classified accurately, while maintaining minimal false positives (less than 20% of TOI)."</li> </ul>

# UltraTEMA: Single-Pass UW EMI detection and classification system

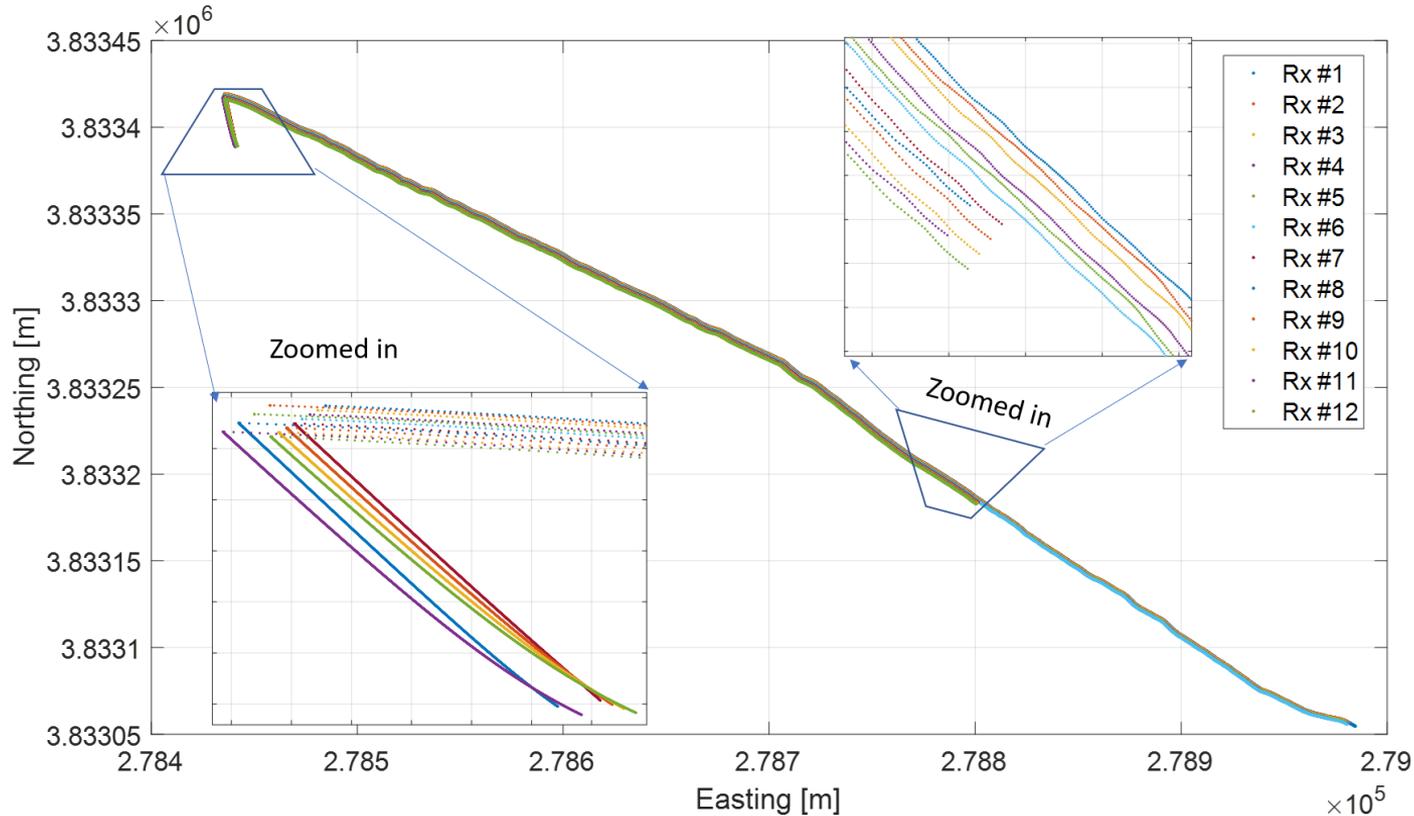

The UltraTEMA system consists of three transmitter coils and twelve vector receiver sensors. It measures complete EMI response of a target at each dynamic data point and provides 108 data value at each  $n^{\text{th}}$  ( $n=1,2, \dots, 25$ ) time gate.

# Data Inversion Scheme

Using four receiver sets for each dynamic data inversion

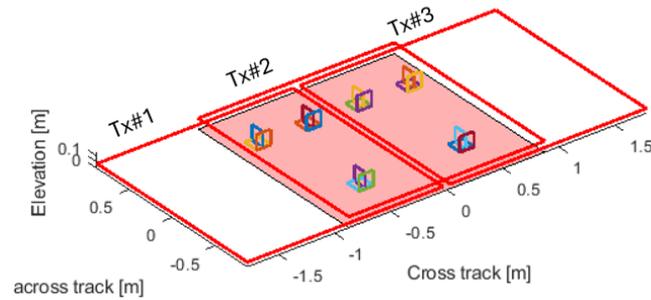

•**Set #1:** Complete array of 12 triaxial receivers

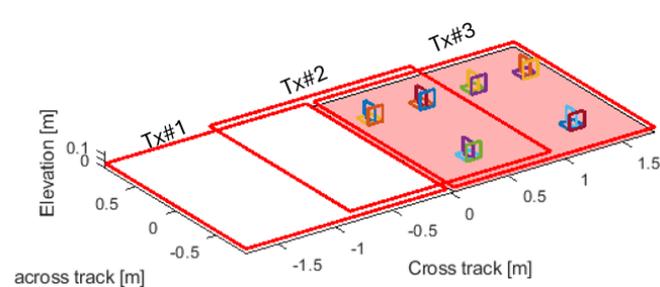

•**Set #2:** Subset of triaxial receivers 1–6

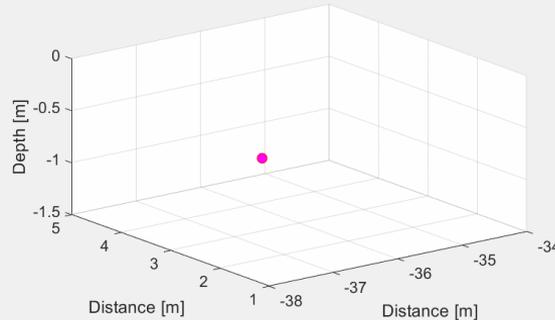

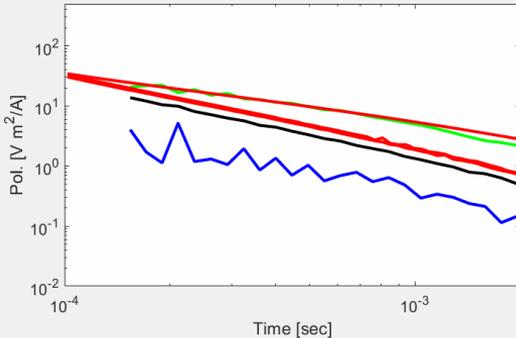

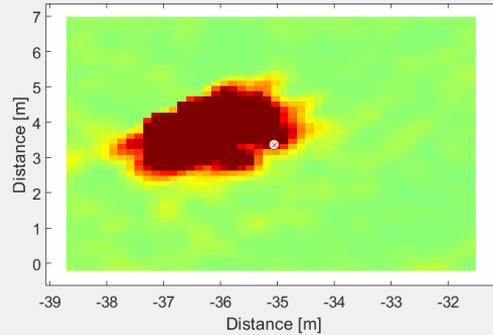

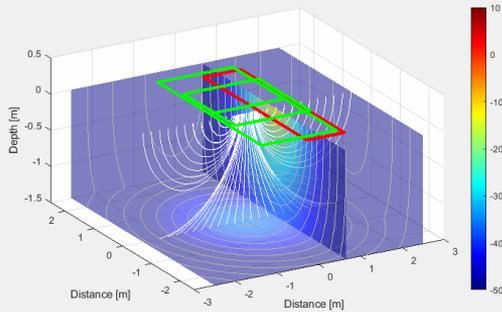

•**Set #3:** Subset of triaxial receivers 4–9

•**Set #4:** Subset of triaxial receivers 7–12

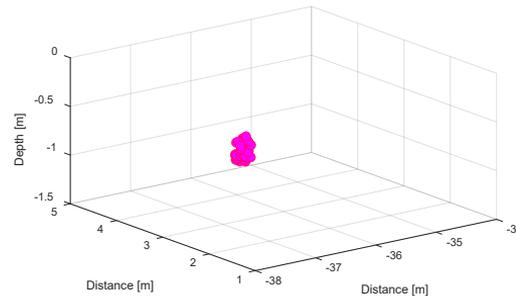

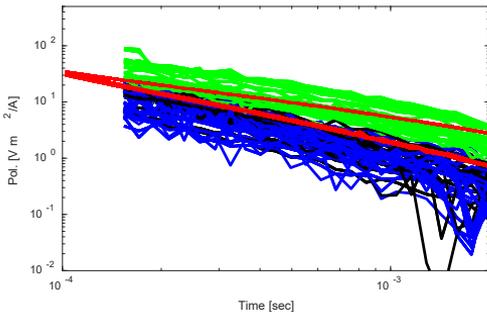

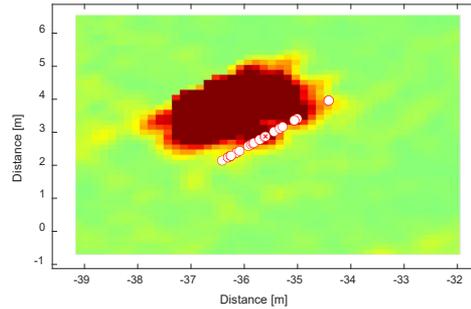

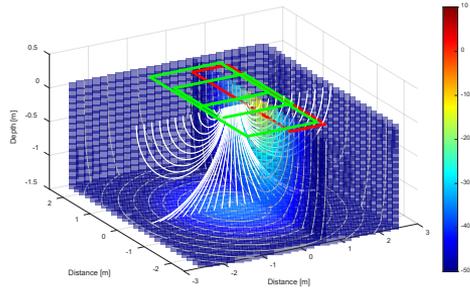

# Results: Single-Pass data processing

- A set of dynamic data points is identified around the target.
- An objective function is defined as the simple difference between two data points.
- The target's location and classification features are extracted from each objective function.

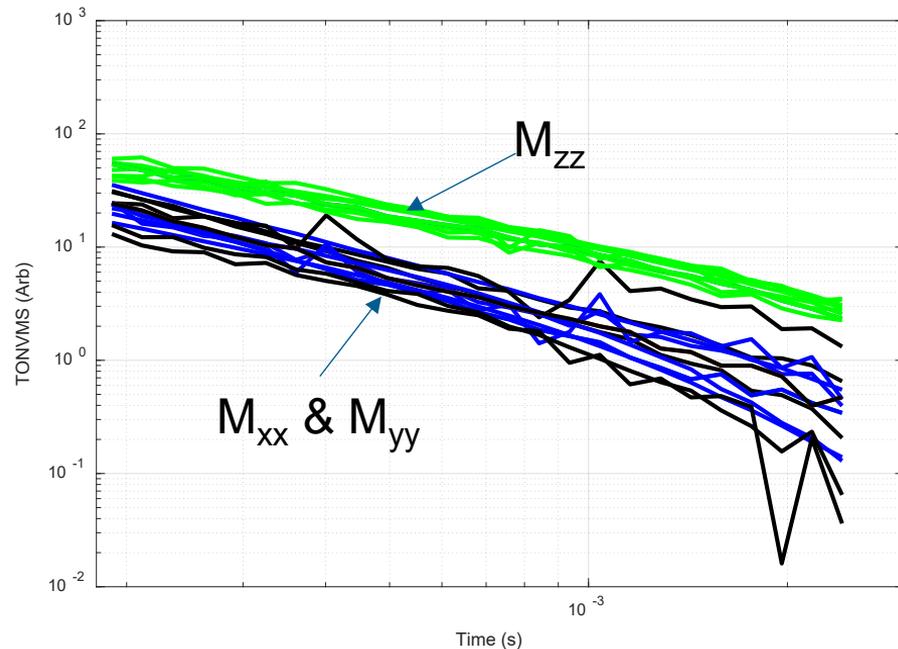

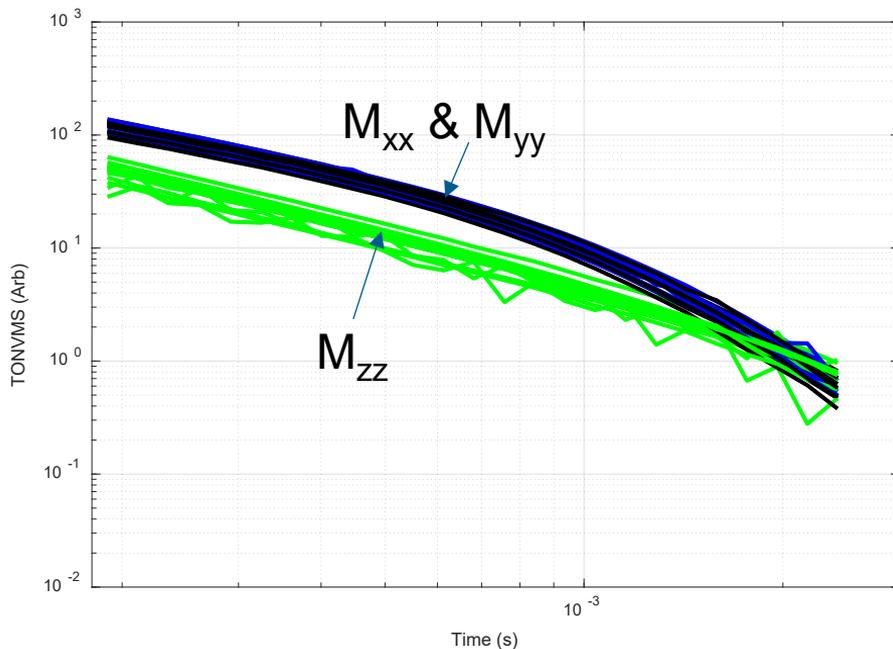

# Results: Clustering polarizabilities and locations

- The extracted noisy effective polarizabilities and their corresponding locations are discarded.
- The remaining locations are grouped into clusters.
- Within each cluster, the effective polarizabilities are sorted and stacked.

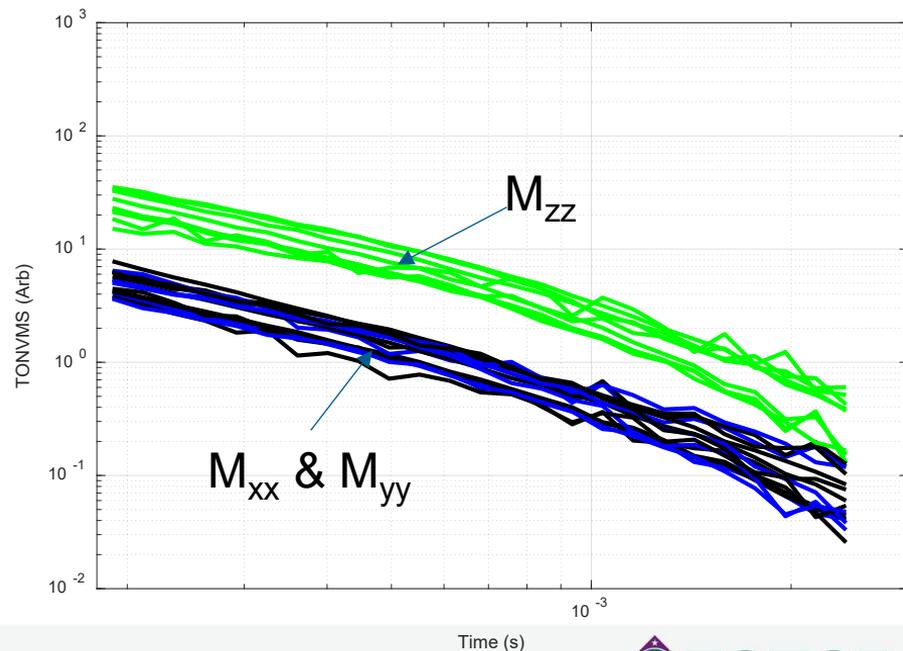

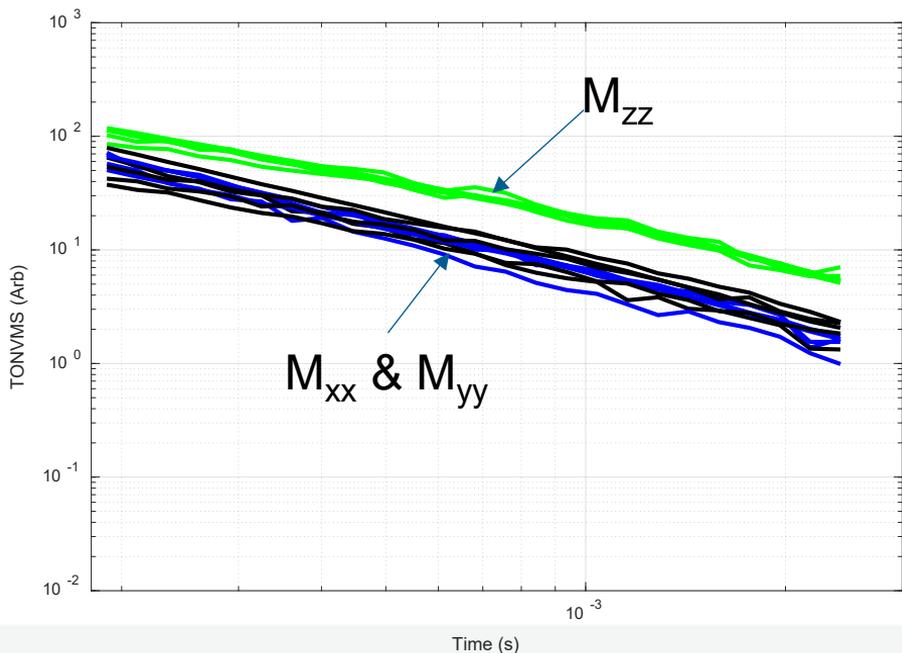

# Results: Extracting Classification Features of Targets

## Extracted effective polarizabilities

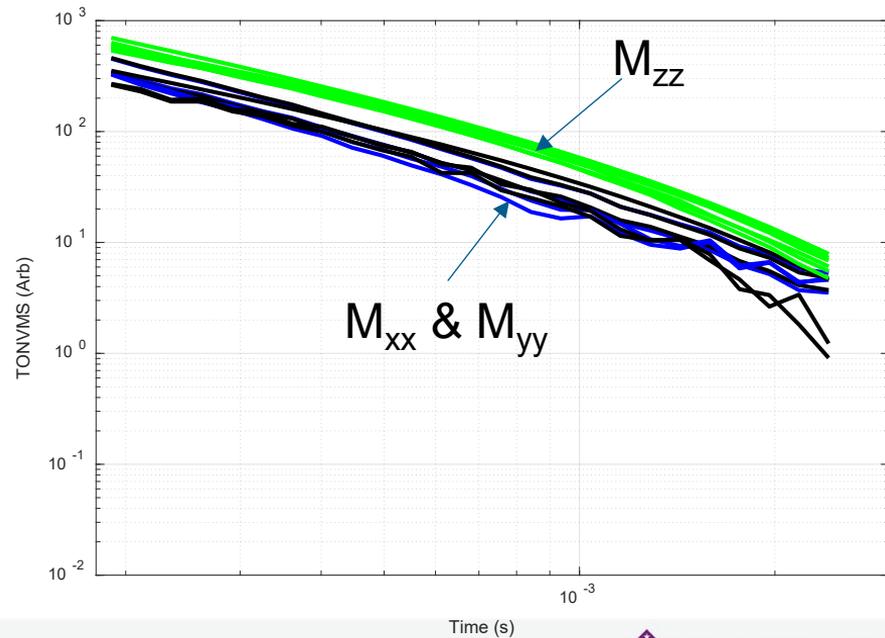

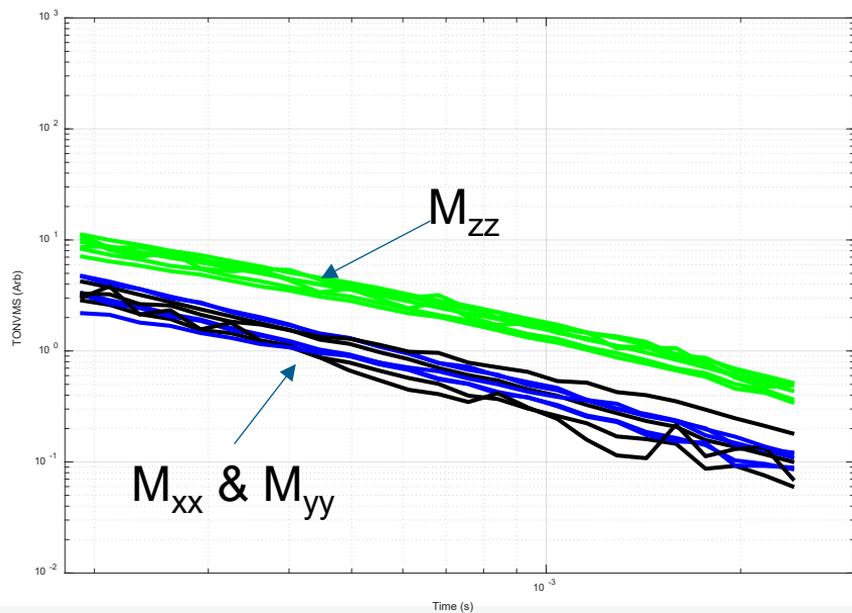

# Results: Extracting Classification Features of Targets

## Extracted effective polarizabilities

# Issues

- GPS locations

# Next Steps

- Classify the targets.
- Evaluate the models' classification performances for detecting and classifying UW targets.
- Submit a journal paper by 03/31/2026
- Submit the final report by 7/31/2026.

# Technology Transfer

- The numerical models and classification results will be presented at conferences and published in peer-reviewed journals.
- The final report will provide a detailed overview of the technologies and results for the broader UXO community.
- Additionally, the UW data processing modules and target classification algorithms will be adapted for use with other UW EMI systems.

# BACKUP MATERIAL

These charts are required and will be used by the Program Office but may not be presented.
